

# Nonlinear Optimization in R using `nlopt`

Rahul Bhadani\*

08 January 2021

## Abstract

In this article, we present a problem of nonlinear constraint optimization with equality and inequality constraints. Objective functions are defined to be nonlinear and optimizers may have a lower and upper bound. We solve the optimization problem using the open-source R package `nloptr`. Several examples have been presented.

## 1 Introduction

Often in physical science research, we end with a hard problem of optimizing a function (called objective) that satisfies a range of constraints - linear or non-linear equalities and inequalities. The optimizers usually also have to adhere to the upper and lower bound. We recently worked on a similar problem in Quantum Information Science (QIS) where we attempted to optimize a non-linear function based on a few constraints dictated by rules of physics and mathematics. Interested readers may find our work on Constellation Optimization for Phase-Shift Keying Coherent States [Bhadani and Djordjevic, 2020] where we optimized mutual information for QuadriPhase-Shift Keying (QPSK) based on a set of constraints.

While chasing the problem of non-linear optimization with a set of constraints, we found out that not all optimization routines are created equally. There several libraries available in different languages such as python (scipy.optimize), Matlab (fmincon), C++ (robotim, nlopt), and R (nloptr). While the list for optimization routine presented here is not exhaustive, some of them are more reliable than others, some provide faster execution than others and some have better documentation. Based on several key factors, we find nloptr, implemented in the R language to be most suitable for nonlinear optimization. nloptr uses nlopt implemented in C++ as a backend. As a result, it provides the elegance of the R language and the speed of C++. The optimization procedure is performed quickly in a fraction of seconds even with a tolerance of the order of  $10e-15$ .

## 2 Nonlinear Optimization Problem

A general nonlinear optimization problem usually have the form

$$\min_{x \in \mathbb{R}^n} f(x)$$

such that

$$g(x) \leq 0$$

$$h(x) = 0$$

$$x_L \leq x \leq x_U$$

where  $f$  is an objective function,  $g$  defines a set of inequality constraints,  $h$  is a set of equality constraints.  $x_L$  and  $x_U$  are lower and upper bounds respectively. In the literature, several optimization algorithms have

---

\*The University of Arizona, [rahulbhadani@email.arizona.edu](mailto:rahulbhadani@email.arizona.edu)

been presented. For example, MMA (Method of moving asymptotes) [Svanberg, 1987] supports arbitrary nonlinear inequality constraints, (COBYLA) Constrained Optimization BY Linear Approximation [Powell, 1994], (ORIG\_DIRECT) DIRECT algorithm [Finkel, 2003]. Optimization algorithms that also support nonlinear equality constraints include ISRES (Improved Stochastic Ranking Evolution Strategy) [Runarsson and Yao, 2000], (AUGLAG) Augmented Lagrangian Algorithm [Conn et al., 1991]. A full list of such methods can be found on the nlopt C++ reference page at [https://nlopt.readthedocs.io/en/latest/NLopt\\_Reference/](https://nlopt.readthedocs.io/en/latest/NLopt_Reference/).

In the rest of the article, We provide several examples of solving a constraint optimization problem using R. We use R Studio that combines R compiler and editor. R Studio also provides a knitr tool which is great for writing documentation or articles with inline code which can also generate a latex source code and a pdf file. Most of the example presented here has been modified from test suites used to validate functions in `nloptr` R package.

### 3 Installation and loading the library

Installation of `nloptr` in R is fairly straightforward.

```
install.packages("nloptr")
```

```
library('nloptr')
```

### 4 Example 1: Optimization with explicit gradient

In the first example, we will minimize the Rosenbrock Banana function

$$f(x) = 100(x_2 - x_1^2)^2 + (1 - x_1)^2$$

whose gradient is given by

$$\nabla f(x) = \begin{pmatrix} -400x_1(x_2 - x_1^2) - 2(1 - x_1) \\ 200(x_2 - x_1^2) \end{pmatrix}$$

However, not all the algorithms in `nlopt` require explicit gradient as we will see in further examples. Let's define the objective function and its gradient first:

```
eval_f <- function(x)
{
  return ( 100 * (x[2] - x[1] * x[1])^2 + (1 - x[1])^2 )
}

eval_grad_f <- function(x) {
  return( c( -400 * x[1] * (x[2] - x[1] * x[1]) - 2 * (1 - x[1]),
    200 * (x[2] - x[1] * x[1]) ) )
}
```

We also need initial values

```
x0 <- c( -1.2, 1 )
```

Before we run the minimization procedure, we need to specify which algorithm we will use. That can be done as follows:

```
opts <- list("algorithm"="NLOPT_LD_LBFGS",
"xtol_rel"=1.0e-8)
```

Here, we will use the L-BFGS algorithm. Now we are ready to run the optimization procedure.

```
# solve Rosenbrock Banana function
res <- nloptr( x0=x0,
eval_f=eval_f,
eval_grad_f=eval_grad_f,
opts=opts)
```

See the result

```
print(res)

##
## Call:
## nloptr(x0 = x0, eval_f = eval_f, eval_grad_f = eval_grad_f, opts = opts)
##
##
##
## Minimization using NLOpt version 2.4.2
##
## NLOpt solver status: 1 ( NLOPT_SUCCESS: Generic success return value. )
##
## Number of Iterations.....: 56
## Termination conditions:  xtol_rel: 1e-08
## Number of inequality constraints:  0
## Number of equality constraints:  0
## Optimal value of objective function:  7.35727226897802e-23
## Optimal value of controls: 1 1
```

The function is optimized at (1,1) which is the ground truth.

## 5 Example 2: Minimizing with inequality constraint without gradients

The problem to minimize is

$$\begin{aligned} \min_{x \in \mathbb{R}^n} \quad & \sqrt{x_2} \\ \text{s.t.} \quad & x_2 \geq 0 \\ & x_2 \geq (a_1 x_1 + b_1)^3 \\ & x_2 \geq (a_2 x_1 + b_2)^3 \end{aligned}$$

with  $a_1 = 2$ ,  $b_1 = 0$ ,  $a_2 = -1$ , and  $b_2 = 1$ . We re-arrange the constraints to have the form  $g(x) \leq 0$ :

$$\begin{aligned} (a_1 x_1 + b_1)^3 - x_2 &\leq 0 \\ (a_2 x_1 + b_2)^3 - x_2 + 2 &\leq 0 \end{aligned}$$

First, define the objective function

```
# objective function
eval_f0 <- function( x, a, b ){
return( sqrt(x[2]) )
}
```

and constraints are

```
# constraint function
eval_g0 <- function( x, a, b ) {
  return( (a*x[1] + b)^3 - x[2] )
}
```

Define parameters

```
# define parameters
a <- c(2,-1)
b <- c(0, 1)
```

Now solve using NLOPT\_LN\_COBYLA without gradient information

```
# Solve using NLOPT_LN_COBYLA without gradient information
res1 <- nloptr( x0=c(1.234,5.678),
  eval_f=eval_f0,
  lb = c(-Inf,0),
  ub = c(Inf,Inf),
  eval_g_ineq = eval_g0,
  opts = list("algorithm"="NLOPT_LN_COBYLA",
    "xtol_rel"=1.0e-8),
  a = a,
  b = b )
print( res1 )

##
## Call:
## nloptr(x0 = c(1.234, 5.678), eval_f = eval_f0, lb = c(-Inf, 0),
##      ub = c(Inf, Inf), eval_g_ineq = eval_g0, opts = list(algorithm = "NLOPT_LN_COBYLA",
##      xtol_rel = 1e-08), a = a, b = b)
##
##
## Minimization using NLOpt version 2.4.2
##
## NLOpt solver status: 4 ( NLOPT_XTOL_REACHED: Optimization stopped because
## xtol_rel or xtol_abs (above) was reached. )
##
## Number of Iterations.....: 50
## Termination conditions:  xtol_rel: 1e-08
## Number of inequality constraints:  2
## Number of equality constraints:    0
## Optimal value of objective function:  0.544331053951819
## Optimal value of controls: 0.3333333 0.2962963
```

## 6 Example 3: Minimization with equality and inequality constraints without gradients

We want to solve the following constraint optimization problem

$$\min_x x_1 x_4 (x_1 + x_2 + x_3) + x_3$$

s.t.

$$x_1 x_2 x_3 x_4 \geq 25$$

$$x_1^2 + x_2^2 + x_3^2 + x_4^2 = 40$$

$$1 \leq x_1, x_2, x_3, x_4 \leq 5$$

Let's first solve it with gradients

```
eval_f <- function( x ) {
  return( list( "objective" = x[1]*x[4]*(x[1] + x[2] + x[3]) + x[3],
               "gradient" = c( x[1] * x[4] + x[4] * (x[1] + x[2] + x[3]),
                               x[1] * x[4],
                               x[1] * x[4] + 1.0,
                               x[1] * (x[1] + x[2] + x[3]) ) ) )
}

# Inequality constraints.
eval_g_ineq <- function( x ) {
  constr <- c( 25 - x[1] * x[2] * x[3] * x[4] )

  grad <- c( -x[2]*x[3]*x[4],
             -x[1]*x[3]*x[4],
             -x[1]*x[2]*x[4],
             -x[1]*x[2]*x[3] )

  return( list( "constraints"=constr, "jacobian"=grad ) )
}

# Equality constraints.
eval_g_eq <- function( x ) {
  constr <- c( x[1]^2 + x[2]^2 + x[3]^2 + x[4]^2 - 40 )

  grad <- c( 2.0*x[1],
             2.0*x[2],
             2.0*x[3],
             2.0*x[4] )

  return( list( "constraints"=constr, "jacobian"=grad ) )
}

# Initial values.
x0 <- c( 1, 5, 5, 1 )

# Lower and upper bounds of control.
lb <- c( 1, 1, 1, 1 )
ub <- c( 5, 5, 5, 5 )

# Optimal solution.
solution.opt <- c(1.00000000, 4.74299963, 3.82114998, 1.37940829)

# Set optimization options.
local_opts <- list( "algorithm" = "NLOPT_LD_MMA",
                   "xtol_rel" = 1.0e-7 )
opts <- list( "algorithm" = "NLOPT_LD_AUGLAG",
             "xtol_rel" = 1.0e-7,
             "maxeval" = 1000,
             "local_opts" = local_opts,
             "print_level" = 0 )
```

```

# Do optimization.
res <- nloptr( x0          = x0,
              eval_f      = eval_f,
              lb          = lb,
              ub          = ub,
              eval_g_ineq = eval_g_ineq,
              eval_g_eq   = eval_g_eq,
              opts        = opts )

print(res)

##
## Call:
##
## nloptr(x0 = x0, eval_f = eval_f, lb = lb, ub = ub, eval_g_ineq = eval_g_ineq,
##       eval_g_eq = eval_g_eq, opts = opts)
##
##
## Minimization using NLOpt version 2.4.2
##
## NLOpt solver status: 4 ( NLOPT_XTOL_REACHED: Optimization stopped because
## xt看ol_rel or xt看ol_abs (above) was reached. )
##
## Number of Iterations....: 537
## Termination conditions:  xt看ol_rel: 1e-07 maxeval: 1000
## Number of inequality constraints:  1
## Number of equality constraints:    1
## Optimal value of objective function:  17.014017291835
## Optimal value of controls: 1 4.743002 3.821147 1.379409

```

This can be solved differently without gradient as follows:

The objective function is defined as

```

eval_f <- function(x)
{
  return (x[1]*x[4]*(x[1] +x[2] + x[3] ) + x[3] )
}

```

Inequality constraint can be defined as:

$$25 - x_1x_2x_3x_4 \leq 0$$

```

eval_g_ineq <- function(x)
{
  return (25 - x[1]*x[2]*x[3]*x[4])
}

```

Equality constraint can be defined as

```

eval_g_eq <- function(x)
{
  return ( x[1]^2 + x[2]^2 + x[3]^2 + x[4]^2 - 40 )
}

```

Let's specify upper and lower bounds

```
lb <- c(1,1,1,1)
ub <- c(5,5,5,5)
```

Now, define initial values

```
x0 <- c(1,5,5,1)
```

Define options

```
# Set optimization options.
local_opts <- list( "algorithm" = "NLOPT_LD_MMA", "xtol_rel" = 1.0e-15 )
opts <- list( "algorithm"= "NLOPT_GN_ISRES",
"xtol_rel"= 1.0e-15,
"maxeval"= 160000,
"local_opts" = local_opts,
"print_level" = 0 )
```

We use NL\_OPT\_LD\_MMA for local optimization and NL\_OPT\_GN\_ISRES for overall optimization. You can set the tolerance to extremely low to get the best result. The number of iterations is set using maxeval. Setting tolerance to low or the number of iterations to very high may result in the best approximation at the cost of increased computation time.

Finally, optimize

```
res <- nloptr ( x0 = x0,
               eval_f = eval_f,
               lb = lb,
               ub = ub,
               eval_g_ineq = eval_g_ineq,
               eval_g_eq = eval_g_eq,
               opts = opts
             )
print(res)
```

```
##
## Call:
##
## nloptr(x0 = x0, eval_f = eval_f, lb = lb, ub = ub, eval_g_ineq = eval_g_ineq,
##       eval_g_eq = eval_g_eq, opts = opts)
##
##
## Minimization using NLOpt version 2.4.2
##
## NLOpt solver status: 5 ( NLOPT_MAXEVAL_REACHED: Optimization stopped because
## maxeval (above) was reached. )
##
## Number of Iterations....: 160000
## Termination conditions:  xtol_rel: 1e-15 maxeval: 160000
## Number of inequality constraints:  1
## Number of equality constraints:    1
## Current value of objective function:  17.059369054183
## Current value of controls: 1 4.566185 4.038851 1.355593
```

## 7 Example 4: Minimization with multiple inequality constraints without gradients

Our objective function in this case is

$$\min_x x_1^2 + x_2^2$$

such that

$$1 - x_1 + x_2 \leq 0$$

$$1 - x_1^2 + x_2^2 \leq 0$$

$$9x_1^2 + x_2^2 \geq 9$$

$$x_1^2 - x_2 \geq 0$$

$$x_2^2 - x_1 \geq 0$$

with bounds on variables as

$$-50 \leq x_1, x_2 \leq 50$$

Let's write objective function first

```
eval_f <- function(x)
{
  return ( x[1]^2 + x[2]^2 )
}
```

Inequality constraints can be written as

```
eval_g_ineq <- function (x) {
  constr <- c(1 - x[1] - x[2],
             1 - x[1]^2 - x[2]^2,
             9 - 9*x[1]^2 - x[2]^2,
             x[2] - x[1]^2,
             x[1] - x[2]^2)
  return (constr)
}
```

Lower and upper bounds are defined as

```
lb <- c(-50, -50)
ub <- c(50, 50)
```

Initial values are

```
x0 <- c(3, 1)
```

Finally, define options for nloptr

```
opts <- list( "algorithm"      = "NLOPT_GN_ISRES",
              "xtol_rel"      = 1.0e-15,
              "maxeval" = 160000,
              "tol_constraints_ineq" = rep( 1.0e-10, 5 ))
```

Optimize

```

res <- nloptr(
  x0      = x0,
  eval_f  = eval_f,
  lb      = lb,
  ub      = ub,
  eval_g_ineq = eval_g_ineq,
  opts    = opts )
print(res)

##
## Call:
##
## nloptr(x0 = x0, eval_f = eval_f, lb = lb, ub = ub, eval_g_ineq = eval_g_ineq,
##       opts = opts)
##
##
## Minimization using NLOpt version 2.4.2
##
## NLOpt solver status: 5 ( NLOPT_MAXEVAL_REACHED: Optimization stopped because
## maxeval (above) was reached. )
##
## Number of Iterations....: 160000
## Termination conditions:  xtol_rel: 1e-15 maxeval: 160000
## Number of inequality constraints:  5
## Number of equality constraints:    0
## Current value of objective function:  1.99999999963777
## Current value of controls: 1 1

```

While We didn't present the examples with multiple equality constraints, they are very similar to Example 4. However, we sure to select the optimization algorithm as NLOPT\_GN\_ISRES.
